

DYNAMICALLY ILLUMINATED PRODUCT DISPLAY SYSTEM APPARATUS AND METHOD

The present invention relates to electronic product displays. More
5 particularly, the present invention relates to electronic displays of consumer goods
that illuminate the goods displayed on store shelves.

In a commercial environment, it is becoming increasingly difficult to
distinguish one's products on the shelf from other products, many of which often are
the same size and use many of the same colors in the packaging in an attempt to
10 "knock off" purchases of one's product by confusing the consumer. Although certain
shades of colors under strict circumstances have been trademarked, this is very
difficult to obtain and normally could not be acquired for common colors of product
packaging.

Sometimes manufacturers have arranged coupon dispensers that are attached
15 to the shelf, with the dispenser having a blinking light and/or making a sound to catch
the attention of a shopper. The hope is that with the advantage of dispensing a
coupon at the product site, the consumer will be enticed to purchase that particular
brand due to the added savings. However, there is a limit as to how many coupon
dispensers can be displayed in a store, and even so, the product itself is not being
20 displayed any differently than other competing products. In fact, products today are
not displayed very differently than they were in the first supermarkets at beginning of
the 20th century.

Accordingly, there is a need in the art to improve the display of items in a
store that is in line with the taste of modern shoppers. Moreover, many marketers are
25 now trying to move shopping to another level, i.e. "a shopping experience"; this is
particularly true of stores such as cosmetic stores.

The present invention provides a system, method, and a product packaging
that is heretofore unknown in the art. According to the present invention, the product
packaging is dynamically illuminated.

30 According to an aspect of the invention, an electroluminescent material that is
arranged on a surface of the packaging is connected via conductive ink (printed
conductive ink) to a pair of contacts on the lower portion or back of the packaging.
When a power source comes into contact with pair of contacts, the electroluminescent
material lights up, thus illuminating the product package.

The illumination of the product package may comprise a background hue, or the drawings on the package could be a print screened logo on the front of the box with the conductive ink, so that the product displays its logo in luminescence.

5 In another aspect of the invention, nano-wire leds could also be arranged on the box to form a design pattern. Such nano-leds perform essentially as pixels in the primary colors of red, blue and green, and can be used to make virtually any color combination.

In another aspect of the invention, a method involves the product packaging being used to display moving images and text, with advertising slogans and other
10 messages being displayed across the front of the packages.

In yet another aspect of the invention, a plurality of shelves wired with electronic contacts are adapted to receive a plurality of product packages that are adapted for illumination. The packages can be boxes, bottles, jars, etc. If the packaging is transparent, the actual product can be illuminated. The packages are
15 stocked on the shelves and essentially form a matrix of pixels, with each individual package representing a pixel or group of pixels. A control unit is programmed to either illuminate the packages, display a stationary message, or provide a "rolling message" that cycles its way through the path of the lighted packages.

The control unit can be programmed to vary the amount of illumination of
20 certain boxes on the shelf, so that certain stock which is more desirable for a store to sell first can be illuminated the most, wherein less profitable stock could be illuminated but have a lower degree of brightness. In addition, perishable items could be more brightly illuminated so as to induce their purchase ahead of other items on the adjacent shelves

25 Fig. 1 is an illustration of an electroluminescent packaging system according to a first aspect of the present invention.

Fig. 2 illustrates a second aspect of the present invention, wherein the shelf is formed with an angle to always keep an electro-illuminated package at the front of the shelf.

30 Fig. 3 illustrates a plurality of products that are illuminated as though they were individual pixels in a matrix.

It is to be understood by persons of ordinary skill in the art that the following descriptions are provided for purposes of illustration and not for limitation. An artisan

understands that there are many variations that lie within the spirit of the invention and the scope of the appended claims. Unnecessary detail of known functions and operations may be omitted from the current description so as not to obscure the present invention.

5 Fig. 1 is an illustration of a first aspect of the present invention. A first package 101 is shown positioned on a shelf 110. It should be noted that as the drawing figures are presented for purposes of explanation and not for limitation, in no way is the present invention limited to rectangular boxes, as the package could take any shape, for example, square, circular, oblong, parallel-piqued, irregular, polygonal,
10 triangular, elliptical. The package might be a bottle, container, fluid-holding vessel, etc. In a best mode, the lower portion of the package is flat so as to be accommodate electrical contact between contacts 115 on the package 101 and contacts 120 on the store shelf 110, with gravity acting as a force that keeps the product package 101 on the contacts 120.

15 Similar to the description regarding the package, the electrical contacts could be vertically arranged on a lower portion of the box, horizontally arranged, diagonally arranged, may comprise circular or semi-circular contact area areas and could be recessed in the package, or extend from the package. If the contacts extend from the package, it would be presumed that the shelf 110 may have recessed
20 contacts that accept the extensions protruding from the package 101. Although two contacts are shown on the lower portion of the package 101, there could be a plurality of contacts, for example, in which the voltages add, such as a series connection of 1.5 volt contacts that are additive so as to obtain 6 volts, or 9 volts, etc. Again, the 1.5 and 6 volt values are mentioned for explanatory purposes only, with the actual
25 voltages being the values best-suited for use with the electroluminescent ink or display material. Low voltage contacts that are additive might be preferable for purposes of safety.

 The shelf 110 may include fuses, fusible links and/or circuit breakers (not shown) between sets of contacts 120 so as to insure the safety of consumers and
30 store employees in the case of product leakage, if the product, for example, is a conductive liquid, so as to prevent shorting out the shelf portion. Also, other products adjacent the electroluminescent product could also leak, or an item having a completely metallic bottom, such as a can of coffee, could be placed on the shelf inadvertently by a consumer and short the strips of contacts 120, as shoppers

sometimes take items out of their wagons and deposit them in other areas of the store, almost at their whim.

As shown in Fig. 2, the shelf 210 may be inclined so that when a first package is removed, another package containing the electroluminescent material shifts or slides downward by gravity and makes contact with the shelf contacts 120. Item 201 will slide downward into the spot currently held by package 101.

The package 101 will have the electroluminescent material preferably on its face. Such material includes but is not limited to electric ink, or ink mixed with an electroluminescent material that will light up after being exposed to a predetermined voltage. There are known substances that turn color, such as white to black, or blue to red, upon being exposed to a changing voltage level. Alternatively, small surface mounted LEDs, including but not limited to nano-leds, could be mounted on the surface of the box. A conductive path from the electrode contact to the leds and back down to a return or ground contact is one way that the package could be wired. There would be relatively low costs involved with wiring.

The type of message displayed could be the standard logo that is on the package, only it is now illuminated with background light, flashing light, or colored light. In addition, the lights could spell out the product name, or they could be a lighted replica of the logo. Finally, the package could actually display messages, such as a rolling or moving message, that could involve other packages adjacent the package 101.

Figure 3 shows another aspect of the invention, wherein a "wall" of packages 301 are stocked, with select ones turning on and off as though they are in a sense, giant pixels or a plurality of large pixels. There are as series of shelves 310 having electrical contacts 320 similar to those shown in Figs. 1 and 2, except that a controller 325 controls turning on and off the voltage that illuminates the electroluminescent material 305 of the packages 301 to create the lighted pixel effect. The shelf may optionally contain a sensor 307 including but not limited to an electric eye, which could be a simple infrared or photodiode sensor. When a customer approaches the shelf, the system would power on and light up. When no customers are sensed, the system would either power down fully or partially to a standby status, so as not to waste electricity. The sensor would signal the controller 325 when a shopper is detected within range of the display.

Not only can messages about the products be displayed, but words such as "SALE! 20% OFF" or the actual price could be displayed. Also, information about product content could be displayed, such as "all natural" "vitamin fortified" "for thinning hair" or slogans associated with the product, such as "help build bodies twelve ways".

In another aspect of the invention, certain rows or packages may have higher degrees of illumination so as to "push" or increase the possibility that a consumer chooses a package from the more brightly light row or package. More profitable items could be illuminated more than, for example, less profitable items. In this case of perishable items, those items closest to expiration dates could be illuminated more than newer stock, or have different messages displayed on them.

Various modifications may be made by persons of ordinary skill in the art to the present invention that would lie within the spirit of the invention and the scope of the appended claims. For example, the product package does not just means packaging, it make comprise a label on a bottle or jar, or an identifying tab arranged on, or part of the product. The messages displayed can be stationary, blinking, or dynamic, meaning that they "roll" across the matrix of pixels (i.e. the letters are shift from left to right across to adjacent packages of product, or even from right to left if desired). There may be a plurality of messages, or just one large message displayed. The lights can be any color, multi -color, and if illuminating the background of a product, different colors. Different amounts of illumination can be provided to the individual packages, for example, to place particular emphasis on certain predetermined packages either because of their expiration date, profitability, need to sell to reach quote, etc.etc.
